

Data Flow

The information is processed through an organized sequence that starts with user actions and moves through several system operations.

First, users launch the application, view the menu, and add food to their cart. As users edit or continue to checkout, providing payment and personal information, the system then verifies and updates the cart.

The system creates order data and assigns a pickup time after payment is completed through the payment channel and authorized. After that, notifications are sent to the restaurant (order email) and the user (confirmation email). The user receives a payment failure alert if the payment is rejected. The online ordering lifecycle is streamlined by

this flow, which guarantees transparent communication outputs, backend processing, and user inputs. Standards to consider are PCI as individuals credit card information is being input, sometimes stored, and moved.

Process Flow

The process flow map illustrates how user and system actions interact to complete an online food order. The process begins when the user accesses the application, browses the menu, and adds items to the cart. The system responds by updating the cart and allowing the user to view, edit, or delete items. Once the user proceeds to checkout and enters personal and payment information, the system validates the cart and processes the payment through a secure payment gateway. If payment is approved, the system generates order details and a pickup time. Notifications are automatically sent to both the user (confirmation email) and the restaurant (order email), finalizing the process with an "Order Confirmed" status. If the payment fails, the user is notified immediately. This flow ensures a seamless transition from user input to system response, supported by policy based data handling and compliance as described in the transcripts.
